[4] Injections, USP 28 page 2201 · 2(1): 2201 · 3. . Even with intensive and correct postoperative care, 20--30% of children may develop early wound dehiscence after TKA. Not only the wound healing, but also wound strength is markedly reduced in these children.^[@bibr10-0300060519874539]^ However, we found that the DASH scores of the study patients were not significantly higher than those reported in other studies on total knee arthroplasty in China. In our study, the patient-reported outcome and the DASH score improved for all of the patients. Compared with the normal development of the knee joint, the articular cartilage, menisci, and ligaments were injured in patients with knee dislocation, and these factors were closely related to the dysfunction of the knee joint. Knee pain, joint instability, osteoarthritis, joint effusion, and arthrosis of the affected knee were the main manifestations of knee dislocations. A previous study reported that long-term knee dislocation could cause cartilage degradation and could lead to premature osteoarthritis.^[2d92ce491b
