Mach3 Modeltrans has been. Hardware out of the box:Conventional data recording technology, while capable of achieving high storage density, is frequently too costly, inflexible, and slow. In contrast, computing technology, while having a lower overall cost, is at present very flexible but too low in storage density to achieve the required storage capacity. Although magnetic storage offers the highest storage density, its inflexibility and slow access time limit the usefulness of conventional magnetic storage. Optical storage, while offering improved flexibility and much higher transfer rates, is also too costly to be a practical alternative. Conventional magnetic recording employs a data encoding scheme referred to as NRZI (Non Return to Zero Inverted). In this scheme, data is encoded by switching the polarity of each bit of the data. When the polarity of a bit is inverted, a magnetic domain is formed which permanently leaves a remnant magnetization. The data recorded in this form may be read by the demagnetization process used in conventional magnetic recording. Because demagnetization, if it occurs, is permanently recorded, there is no writing over existing data. One of the features of this encoding scheme is that data patterns, so recorded, have generally been self-synchronizing; i.e., if a stream of data, as recorded, is simply read back, the readout will begin in synchronization with the start of each bit. Non-return-to-zero recording requires that the domain size remains fixed while the magnetic flux is reversed. Consequently, non-return-to-zero recording provides a relatively low domain stability. Non-return-to-zero recording requires that the domain size remains fixed while the magnetic flux is reversed, and consequently, non-return-to-zero recording provides a relatively low domain stability. Accordingly, there have been a number of approaches to reducing the size of data bits. One approach is to record the data in bits that are shorter than the minimum time duration that is normally required to stabilize a magnetic domain. Another approach is to use multiple tracks to record the data bit. Some prior art approaches use a different writing scheme, i.e., by the formation of a magnetic domain in a film
