Integrated over 5 years research across UC Berkeley and Jackson School of Geosciences in Santa Barbara, California, has discovered a long-term link between the properties of rocks found on Earth and the probability of plate collisions, triggering earthquakes. The study provides new evidence for the ability of Earth's interior structures to feed back to change the probability of earthquake occurrence. Led by four authors, including two UC Berkeley researchers, the findings are published in Nature Geoscience. "We studied ancient rocks on Earth that show evidence of past plate collision," said study co-author Junwei Zhang, a UC Berkeley graduate student in geology and planetary science, and lead author of the study. "This study demonstrates that the probability of plate collision is related to the presence of certain structural features in a sample's rock, such as the hardness of the rock's mineral phase or the degree of crystallinity." The researchers applied a statistical technique to a compilation of rock data collected since the beginning of sedimentary rock formation on the Earth's surface more than two billion years ago. "We found that, on average, the mineralogy and crystallinity of rocks formed from the collision of two plates have a stronger correlation to plate collision probability than do the properties of rocks formed through other processes, such as continental rifting and volcanic activity," said co-author Zongfang Li, UC Berkeley professor of earth and planetary science. "Among the most surprising findings," said co-author James Rink, a UC Berkeley professor of geosciences and planetary science and the Howard Hughes fellow at Jackson, "is the finding that the very youngest rocks, formed

The see is a titular bishopric. Mariana de Guzmán Guzmán was a nun, founder of a convent of Nuns in Salamanca. On the basis of the book Salamancas, a manuscript in Salamanca in her hand, written between 1435 and 1438, she was venerated as a saint in the mid-16th century. The
